

Generator application of the Deye string inverter setup guide

If there're several inverters paralleling operation in a plant, also it can use 1pcs meter to realize zero export function. For example, if there're 3pcs inverters paralleling operation in the system with 1pcs meter. We need to setup 1pcs inverter as the master and others setup as slaves. And, all of them need to connect to the meter via RS485. Below is the system diagram and configuration of the system.

Note: Currently the Max number of on-grid inverters (3phase) connects 1pcs meter is 10. More info please contact Deye.

Exp_Mode: AVG or Min .

1, **Min** : in this mode (minimum mode), the inverter will give output power according to the smallest load power of three phase. For example, L1 load power: 1kW, L2 load power: 2kW, L3 load power: 3kW, then the inverter output power is $1kW * 3 = 3kW$.

AVG: in this mode (average mode), the inverter will give output power according to the total load power of three phase.

For example, L1 load power: 1kW, L2 load power: 2kW, L3 load power: 3kW, then the inverter output power is $(1kW + 2kW + 3kW) / 3 = 6kW$.

2, **CT_Ratio**: CT ratio of meter. When using meter with external CT, we need to setup this parameter correctly. Otherwise, the meter can't show the accurate data.

3, **MFR**: it is used to choose meter type or inverter recognize the meter type automatically. For the meter communication address need to setup as 001.

MFR Auto: inverter will recognize the meter type automatically.

MFR CHNT: if using the CHNT meter then choose CHNT.

MFR EASTRON: if using the EASTRON meter then choose EASTRON.

4, **Feedin (KW)**: in the zero-export mode for several inverters connected one meter, when the load power is satisfied, it allows the external Power feed into grid. For example, if the inverters power is 100W, the load power is 50W and Feedin is 20KW, the inverter will give output power of 70KW.

5, **Shunt**: used to setup the inverter as master or slave in the system which has more than 1 unit connect to one meter.

6, **ShuntQTY**: number of the inverters in the parallel system with meter.

7, **Generator**: ON/OFF.

8, **G.CT**: CT ratio of meter for the generator. When using meter with external CT, we need to setup this parameter correctly. Otherwise, the meter can't show the accurate data.

9, **G.MFR**: it is used to choose meter type or inverter recognize the meter type automatically when the generator is connected. For the meter communication address need to setup as 002.

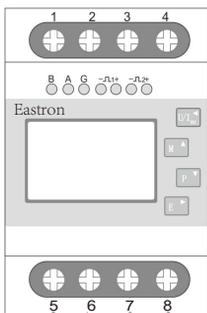

10, **G. Pout %**: the Min. output power of the generator rated power in %.

11, **G.cap**: generator capacity, set upper limit 999KW.
